20

21 **Abstract**

22 The Scientific Reform Movement has highlighted the need for large research teams with
23 diverse skills. This has necessitated the growth of professional team infrastructure roles
24 (TIRs) who support research through specialised skills, but do not have primary
25 responsibility for conceiving or leading research projects. TIRs such as Lab Technicians,
26 Project Managers, Data Stewards, Community Managers, and Research Software
27 Engineers all play an important role in ensuring the success of a research project, but are
28 commonly neglected under current reward and recognition procedures, which focus on the
29 *individual* academic researcher instead of the *teams* involved.

30 Without meaningful identification and recognition of TIR contributions, we risk reinforcing the
31 conceptual and practical division between academic researchers and TIRs. This situation is
32 inequitable and detrimental to the research enterprise: the limited potential for career
33 advancement for TIRs may cause them to leave for other occupations, ultimately leading to
34 a loss of institutional skill, expertise, and memory.

35 This contribution explores the evolution of specialist TIRs and the status of these positions in
36 various settings. We provide three case study descriptions of TIR activities, so that readers
37 may become more familiar with the breadth and depth of their work. We then propose

38 system level changes designed to embed meaningful recognition of all contributions.
39 Acknowledging the contributions of all research roles will help retain skill and expertise, and
40 lead to collaborative research ecosystems that are well-positioned to address complex
41 research challenges.

45

46 **A take-home message**

47 The Scientific Reform Movement has highlighted the need for large research teams with
48 diverse skills. This has necessitated the growth of professional team infrastructure roles
49 (TIRs) who support research through specialised skills. TIRs play an important role in
50 ensuring the success of a research project, but are neglected under current reward and
51 recognition procedures. We provide three case studies of TIR activities and propose system
52 level changes to recognise TIR contributions. Acknowledging the contributions of all
53 research roles will help retain skill and expertise, and lead to collaborative research
54 ecosystems that are well-positioned to address complex research challenges.

55

56 **1. Introduction**

57 The social and technological developments of recent decades have reinforced the notion of
58 science as a team-based enterprise. As we tackle increasingly complex scientific questions
59 (Coles et al., 2022), we leverage the strengths of diverse research teams, recognising that
60 we cannot solve the significant challenges of our time through isolated endeavours. Over
61 5,000 authors across the globe collaborated in the detection of the Higgs Boson at CERN
62 (Castelvecchi, 2015); successful climate models require expertise in atmospheric physics,
63 soil science, meteorology, and more (Huebner et al., 2017); appropriate application of
64 artificial intelligence requires integration with moral and ethical philosophy (Jobin et al.,
65 2019). With increasing collaboration and growing research complexity, new specialised roles
66 have emerged to support research processes. We call these *team infrastructure roles*
67 (TIRs). TIRs bring vital expertise to the process of research, but they are not well integrated
68 in traditional academic organisational structures.

69

70 There are two primary groups of labourers in research: those who have traditionally been
71 awarded manuscript authorship (“academic researchers”), and those who *contribute* to the
72 research process but do not partake in the *credit economy of science*¹ (Zollman, 2018)
73 (“everyone else”). The credit earned within this economy is codified through the prestige of
74 publishing in widely read and cited academic journals, obtaining grants, and winning prizes.
75 This prestige further acts as a social signal of an academic researcher’s aptitude, bringing
76 further rewards in the form of downstream funding success and access to high-status jobs
77 (Huebner & Bright, 2020).

78

79 Those who contribute to the research process but do not participate in the credit economy²
80 — such as laboratory technicians, project managers, grant officers, finance managers,
81 privacy officers, patent officers, and internal review board members (Heffner, 1979)— are
82 known collectively as “professional service staff” or “research professionals”. Their position
83 in between supporting roles and academic researchers has been referred to as the “third
84 space” (Whitchurch, 2008). While some contributions of these roles may appear to be solely
85 bureaucratic, one cannot deny the value of a skilled project manager, finance manager or
86 technician in handling their respective responsibilities. Here, we define these positions as
87 “team infrastructure roles” (TIR), making explicit their structural function in the research
88 process. We provide some examples of TIRs in section 3.

89

90 The emergence of new TIRs has introduced unmapped complexity into the academic
91 ecosystem, particularly in relation to recognition, reward, and development. We argue that
92 successful integration of TIRs in the academic system will require naming, exploring, and
93 resolving of frictions associated with these new roles.

94 **2. Challenges**

95 *2.1 Lack of autonomy within TIR roles*

96 Academic researchers are afforded substantial freedoms in determining their career paths.
97 This stems from historical positioning of academic researchers as “appointees” who perform
98 scholarship as a public duty, rather than “employees” who are a means of production for a
99 university (Finkin & Post, 2011). This legitimises autonomy in the management of day-to-day

¹ Note that the credit economy of science is not field-specific but operates across both Science, Technology, Engineering, Maths and Medicine (STEMM) and Social sciences, Humanities, and the Arts for People and the Economy (SHAPE) disciplines..

² We acknowledge that our perspective is informed by our academic experience in the US and Europe. The challenges, case studies and changes we suggest may be less applicable, or necessary, in other contexts.

100 activities and professional development (Wolf & Jenkins, 2021), and contributes to an
101 internally recognised credit system.

102

103 In contrast, many TIRs are employed as “technical staff”, with a specific remit in their job
104 description to perform support activities, governed by the requirements of academic
105 researchers or the broader goals of the research institute. Consequently, pursuing projects
106 or publications outside of this support remit can be seen as a distraction. This lack of
107 autonomy limits the ability of TIRs to prioritise the growth of their skills alongside evolving
108 research disciplines or methodology, constrains their opportunities for progression towards
109 leadership roles, and ultimately squanders their ability to inform the direction of the research
110 agenda.

111 *2.2 Limited formalisation of career pathways*

112 Many TIR career pathways lack clear development paths (Virágh et al., 2019). This is in
113 contrast to academic research careers, where the criteria for promotion up to the highest
114 levels are well documented, clearly advertised, and often supported by formal and informal
115 systems of mentoring. For example, the *Vitae researcher Development framework* (Vitae,
116 2014) maps out academic researchers’ expected skill development across all facets of
117 scholarly activity. Individuals employed in Human Resources or Finance positions can also
118 access industry-specific accreditation and qualifications to support their progression (for
119 example, training offered through the Chartered Institute of Personnel and Development for
120 Human Resources professionals, or the Association of Chartered Certified Accountants for
121 accountants).

122

123 In contrast, the conventional opportunities for career development, such as increasing job
124 responsibility and resulting uplifts in remuneration (UKRI-Research England, 2022; Virágh et
125 al., 2019), are inconsistent for TIRs. Individuals in TIR positions may therefore look outside
126 of the academy for progression, with subsequent departures leading to institutional memory
127 loss (Bossu & Brown, 2018; McInturff & Adenis, 2022). A lack of professional recognition
128 also introduces challenges in funding TIRs, especially where salaries are not competitive
129 with similar roles outside of academia (UKRI-Research England, 2022). The restriction of
130 developmental opportunities, lack of established profiles and compensation, and limited
131 funding routes leave TIRs to act as lone advocates for their own positions, a stressful and
132 complicated task due to their unique niche within the academic organisational structures.

133 *2.3 Prejudice against TIR activities and career choices*

134 The growing availability of TIRs in research institutes means that academic researchers can
135 increasingly “outsource” some of the research responsibilities that were traditionally theirs
136 alone. Passing those tasks to professionals may be viewed as “a hollowing out of [...] what it
137 means [...] to be an academic” (Macfarlane, 2011, p. 71). By this account, whilst
138 specialisation of roles and responsibilities may bring efficiency, it may also negatively impact
139 traditional academic values and identity, reinforcing a toxic working culture geared only
140 towards maximum productivity (Beatson et al., 2021; Limas et al., 2022; Wellcome Trust,
141 2020). Thus, the mere existence of TIRs may be viewed negatively by some within the
142 academy.

143

144 Prejudice can also result from changes to the status of roles within an institution. Harloe &
145 Perry (2005) suggest that moving to a “co-operative form of production” akin to co-creation,
146 rather than one in which TIRs simply facilitate the work of academics, may undermine a
147 “collegial culture” in universities. In this culture, research academics have traditionally had
148 exclusive responsibilities in determining their university’s governance and organisation
149 through engagement with institutional decision-making systems (such as committees). In this
150 view, TIRs may be categorised as yet another non-academic staff member whose increasing
151 influence dilutes academics’ autonomy and authority, and/or increases their already heavy
152 workload. This perspective highlights current tensions in the system: TIRs may be perceived
153 as not sufficiently qualified to exert influence in the system, despite the fact that many TIRs
154 are highly skilled researchers with doctoral degrees and years of academic experience
155 (Teperek et al., 2022; UKRI-Research England, 2022).

156

157 TIRs may also be stigmatised as “failed academics” because they do not pursue traditional
158 academic careers (Gould van Praag, 2022). This parallels the prejudice against “leaving
159 academia” for industry, often viewed as a last resort for those who “couldn’t hack it” (Gewin,
160 2022). Prejudice towards the activities and career choices of TIRs makes it more difficult to
161 enact changes to infrastructure and reward systems which could benefit them. It also
162 contributes to a form of “imposter syndrome”, with the barriers to reward and progression
163 implicitly reinforcing the message that TIRs are of lower status than academic researchers
164 (Sims, 2021; UKRI-Research England, 2022). Relatedly, the prejudice can also go the other
165 way: TIRs may believe that academics’ reluctance to engage with their help is limiting the
166 potential of an institution (Harloe & Perry, 2005). These tensions can negatively impact
167 attempts at institutional change.

168 2.4. Recognition of TIR contributions

169 Academic incentives are often focused on the contributions of the individual, and the image
170 of a “lone academic genius” (Elkins-Tanton, 2021). This is reinforced by prizes awarded to
171 singular “outstanding” academic researchers, the common practice of naming a research
172 group by the lead Professor (for example, the “Smith lab”), and apparent ownership of team
173 members (“[Person X] is *my* PhD student” or “*my* postdoc”). The power to confer authorship
174 is bestowed primarily to the senior researchers(s) and, in many disciplines, only the first and
175 last authors are deemed to have done the actual work. Practically, however, research builds
176 on previous work as well as a diversity of contributions that do not always lead to authorship
177 and are therefore not formally recognised (Coles et al., 2022; Forscher et al., 2020; Shirazi,
178 2014; Tiokhin et al., 2021). By focusing solely on individuals and first/last authorship
179 positions on publications, the academic research system neglects the value of a broader set
180 of contributors - with their own unique skills and expertise (Baum et al., 2022). This results in
181 precarious positions for TIRs, as their work rarely warrants the first or last authorship
182 position valued by the academic system.

183 3. Growth of TIRs

184 Some emerging TIRs have been exemplary in handling the challenges outlined above.
185 These examples may serve to illustrate the utility of making TIR duties, performance
186 expectations and influence more explicit, along with the merits of forming professional
187 communities of practice. These roles have been listed in order of more established
188 (Research Software Engineer) to relatively recent (Research Application Manager). These
189 roles exemplify how well-resourced TIRs can bring substantial value to the academic
190 workflow. In **Table 1** we additionally summarise career trajectories and opportunities for
191 recognition in each role.

192 3.1 Example 1: Research Software Engineer

193 Research software engineering represents an established specialised research role; a hybrid
194 between researcher and programmer which requires expertise in both research and
195 programming. Similar roles have existed for decades with a variety of titles, but the specific
196 title – Research Software Engineer (RSE) – was conceived at Collaborations Workshop in
197 Oxford, UK in 2012 (Hettrick, 2016), followed by the formation of the RSE Association in
198 2013. The rise of RSEs demonstrates the power of naming and defining a role, providing an
199 identity and focal point for action (Sims, 2021). Hettrick (2016) summarises the first four
200 years of actions by the RSE Association, including numerous articles, market analysis, and
201 policy work. Today, there are RSE networks on every continent, an international council of

202 RSE associations, and an emerging, standardised career path for RSEs. This is the result of
203 sustained, organised advocacy efforts by both researchers and RSEs.

204

205 RSEs function both as individuals in embedded roles as well as consolidated groups who
206 provide expertise on a project-by-project basis within their institutions. This “consultant”
207 model provides access to RSE expertise for groups who do not have the budget for longer
208 term investment.

209 *3.2 Example 2: Scientific Community Manager*

210 Scientific Community Managers foster collaboration, engagement, connection, and
211 productivity among members of a community, where a *community* is a group of people
212 united by a common tool, discipline, location, service or interest. Only in recent years the
213 coordination and management of scientific communities has become formalised, as cross-
214 institutional and international collaborations have become more common. The *Center for*
215 *Scientific Collaboration and Community Engagement* (CSCCE) was established in 2016 to
216 provide training, support infrastructure, and advocacy for Scientific Community Managers,
217 formalising it as a distinct professional role (CSCCE, 2022a). The first Community
218 Engagement Fellowship cohort in 2017 kick-started the conversation around the nature of
219 scientific community management and its unique challenges and considerations compared
220 to communities outside academia. The CSCCE provides a space where Scientific
221 Community Managers can receive support, domain-specific updates, and opportunities for
222 collaboration and professional development. The CSCCE is now developing a community
223 manager certification (CSCCE, 2022b), so that individuals who are expected to foster
224 community engagement can perform their role with confidence and a thorough
225 understanding of the technical and theoretical basis of community activities.

226 *3.3 Example 3: Research Application Manager*

227 Research Application Managers (RAMs) bring product thinking and stakeholder engagement
228 to research outputs. For example, RAMs at The Alan Turing Institute address the need for
229 sustainability of research infrastructure, extend existing research outputs and software, and
230 seek opportunities to reuse and reproduce these outputs in new scenarios (The Turing Way
231 Community, 2022b). RAMs think beyond the research project cycle, cultivate a broader
232 understanding of a discipline’s trajectory, and understand the interconnectedness of
233 scientific research more broadly. This role is still emerging as distinct from a Product
234 Manager in industry, or an academic Innovation Officer, with little formal documentation or

235 organised advocacy in place. RAMs represent an interesting example of a newly emerging
 236 TIR which may experience a similar trajectory as RSEs and Scientific Community Managers.

237
 238 **Table 1:** TIR Case Studies described in section 3. The table provides a summary of each role,
 239 whether there is an established professional advocacy organisation, expected career trajectories and
 240 professional development, comparisons to roles outside of research, and how these roles can be
 241 recognised.

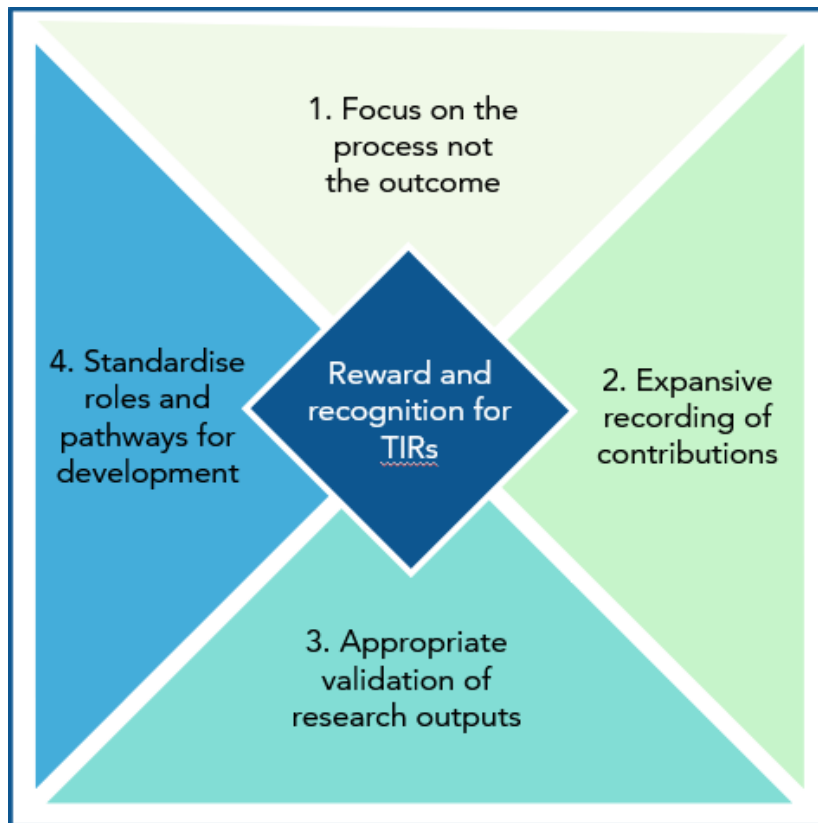

242

	Research Software Engineer (RSE)	Science Community Manager	Research Application Manager
Summary of Role	Creates and/or maintains software specifically intended for research purposes	Fosters collaboration and engagement among a specific scientific community	Guides research projects (including infrastructure) for sustained impact and reuse through user community engagement
Professional Organisation	National and regional RSE associations	CSCCE	None yet
Sources of Professional Development	Software development training; Software Sustainability Institute	Community management training; CSCCE	Product management training
Career Pathways	Increasing rank, management of other RSEs or RSE teams	director of organisations, scientific organisation administration, programme/network management	None yet
Non-research Equivalents	Software development	Community/outreach manager, developer advocate	Developer relations, product manager, developer advocate
Reward/Recognition Opportunities	Conferences, software publications, software citation, awards	Conferences, informal praise, training and development opportunities, contributorship on publications, awards	Conferences, Inter-institute interactions, wider uptake of projects

243

244 **4. Pathways forward**

245 Here we present pathways through the challenges described in section 2, and towards the
 246 successes of the case studies highlighted in section 3. We identify first steps towards a
 247 vision in which all TIRs are appropriately rewarded, recognised, and integrated with the work
 248 and priorities of research academics (**Figure 1**). An appropriate next stage will be the
 249 evaluation of costs and practicality of each intervention in supporting immediate or long-term
 250 change, with iterative piloting and refinement towards the idealised vision.

251

252 **Figure 1:** Summary of proposals to improve reward and recognition for Team Infrastructure Roles
 253 (TIRs).

254

255 *4.1. Focus on the process, not the outcomes*

256 Although research is primarily viewed in terms of knowledge production, we take inspiration
 257 from the values described in the SCOPE framework (INORMS, 2022) and recommend that
 258 individual *outputs* (such as publications, discoveries, technologies) be deprioritised in favour
 259 of elevating the *process*. Focusing on *how* research is produced will additionally centre
 260 actions that improve transparency, reproducibility, and cooperation in academia. In contrast,
 261 a focus on individual outputs encourages implicit or explicit "gaming" of the system, with
 262 production metrics being incentivised over the underlying validity of research works
 263 (Goodhart's law; Goodhart, 1984).

264 A focus on the process also encourages sharing of the artefacts that pave the way to more
 265 finalised research objects. A move to more frequent or continuous publishing will benefit
 266 TIRs and others with precarious contracts, where the lag between contribution and
 267 traditional journal authorship can make it difficult to evidence skills or expertise in a timely
 268 manner. These *incremental publications* (such as protocols, data objects, and preprints) can
 269 also reduce gatekeeping around authorship—research groups may be more willing to

270 acknowledge a named contribution where there is a clearer connection between the work
271 and the published object. For example, a lab technician working on a protocol will have a
272 stronger claim to be a named contributor on a published protocol than a research paper that
273 uses that protocol. Alongside systems that are specific for one type of output (for example,
274 [arXiv](#) for preprints or [PREreview](#) for published peer reviews), general-purpose platforms
275 such as [ResearchEquals](#), [PubPub](#), and [Octopus](#) enable the creation of a timely and
276 persistent record of broad research contributions. By affording attention and credit to a
277 broader range of output types, the primacy of the final journal article in evaluation metrics will
278 be reduced and each contribution will garner respect in its own right.

279 *4.2. An expansive system for recognising contributions*

280 We imagine a future where research is inclusive and participatory, with each contribution
281 being valuable to the process and subsequent outcomes. This requires the acknowledgment
282 that different individuals bring a diverse and meaningful array of skills and expertise,
283 including those from backgrounds that lack traditional academic credentialing. Contributions
284 can be in the form of materially-visible work (for example writing, data collection, software
285 development), workflow improvements, ideation, and more. A thorough and accurate
286 accounting of all contributions will require moving beyond quantifiable metrics such as
287 datasets curated, lines of code written. As TIRs can support the research process in a
288 myriad of ways, integrating qualitative descriptions of their contributions will be necessary to
289 properly recognise their efforts.

290 The Contributor Roles Taxonomy (CRediT; Brand et al., 2015) is an increasingly popular
291 framework for recognising contributions. However, even with 14 codified roles, the CRediT
292 system does not fully address the problem of recognising diverse contributions. As
293 previously noted, it is too common that "research" is synonymous with "peer-reviewed
294 publication", when there are many other contributions that are impactful within the research
295 endeavour. For example, Harris et al. (2020) published on the decades-long collaborative
296 NumPy programming library project. There was a notable lack of gender diversity among the
297 listed authors of the published report (Gallant, 2022), despite gender diversity among the
298 more recent code and documentation contributors (Weber Mendonça, 2020), raising the
299 question of how to recognise indirect contributions. If research is conducted in a version
300 control system that tracks all changes (such as the [Open Science Framework](#)), one might
301 assume all contributions would be observable and easily collated. But such a system will
302 overlook efforts that are not readily recorded in said system (such as coordination and
303 planning efforts, or offline discussions). The Turing Way's '[Record of Contributions](#)' (The
304 Turing Way Community, 2022a) demonstrates one way to recognise all forms of

305 contributions, where indirect contributions can be nominated into the tracking system;
306 namely, using the all-contributors bot (All Contributors, 2022). In addition, systems for
307 tracking impact via citations will need to be much more comprehensive. For example, even
308 with Digital Object Identifiers (DOI) emerging as a de facto standard, a DOI generated using
309 Zenodo is only recorded as a citation if it is discovered in one of Zenodo's indexed data
310 sources; a DOI that is merely listed in an uploaded file may not be recorded as a citation!

311 Furthermore, a focus on publications may not be ideal for recognizing TIR contributions,
312 especially for roles where the primary responsibilities do not include research. Indeed, TIR
313 contributions can extend to include: teaching, training, mentorship, lab supervision, and
314 consultations provided by specialised experts in statistics, data analysis, or software
315 development. These contributions rely on research content expertise, yet are not easily
316 folded into publishable research objects. Although some of these activities are performed
317 within the remit of high-level leadership, appointment to such positions often requires
318 evidence of a "successful research career", ignoring the expertise accumulated in TIR roles.
319 Although it is unrealistic to expect any single system for recognising contributions to be ideal
320 for every context, a credit framework that is customisable for different institutions and locales
321 is an important first step towards addressing these challenges.

322 *4.3. A system to validate research outputs*

323 The above framework presupposes a large expansion in the types of research outputs.
324 However, there may be resistance in recognising these outputs as "valid" because many
325 lack formal systems for external peer review. Indeed, a system which incentivises
326 "productivity" without an assessment of quality (no matter the output type) could lead to
327 decreased trust in research. To ensure the quality of research outputs, and the ability for
328 researchers to build effectively upon each other's works, systems should be established for
329 expert review of all research outputs. Mirroring the peer review system for publications, TIRs
330 could then participate by contributing their experience and skills to the review process.

331 Notwithstanding the complex debates about open peer review (Heesen & Bright, 2021;
332 Ross-Hellauer, 2017), unremitted labour (Aczel et al., 2021), and power dynamics (Huber et
333 al., 2022), peer review can serve a useful purpose in validating research outputs. Realising
334 an appropriate system for peer review of diverse research outputs, however, will require
335 large infrastructural and behavioural shifts. In the case of research software, such systems
336 have already emerged in venues such as rOpenSci (2022), pyOpenSci (Holdgraf et al.,
337 2022), and the Journal of Open Source Software (2022). For other types of outputs, a peer
338 review system would need to be designed to integrate effectively with how the outputs are

339 used. For example, research protocols cannot be easily modified following reviewers'
340 suggestion, so there would have to be a well-specified role or aim for reviewer feedback
341 beyond the suggestion of changes.

342 *4.4. Standardised roles and pathways for career development*

343 As demonstrated in the case studies of **section 3**, and Data Stewards in the Netherlands
344 (Jetten et al., 2021), the trend to professionalise TIRs leads to improvements in the visibility
345 of the work, increased opportunities for training and networking with peers, and role-specific
346 rewards and recognition. We argue that professionalisation also improves the integration of
347 TIRs within research organisational structures. As seen with Research Software Engineers,
348 TIRs may operate in fully independent teams that consult with academic researchers. This
349 structure necessitates leadership responsibility, creating the opportunity for parity in
350 responsibility and compensation between an academic researcher managing a lab group
351 and a TIR managing a team of research support specialists. TIR leadership will also invite a
352 degree of autonomy to direct activities and professional development within the team,
353 including the opportunity to contribute to larger infrastructural change through service on
354 institutional committees. The demarcation of specific responsibilities also supports
355 negotiations to command a salary commensurate with expertise, and make it easier for
356 individuals to move across institutions.

357

358 Professionalisation is, however, hampered by variability in the recognition and career
359 support available to TIRs across institutions. This variability could be addressed through the
360 creation of a new job family and pathway which parallels the development of the distinction
361 between "Research", "Teaching and Research", or "Teaching and Scholarship" grades
362 found in many UK institutions (for example the University of Sussex (2019) and University of
363 St Andrews (2015). Promotion levels in these new job families should equal academic and
364 managerial roles, in contrast to the Technical and Operational or Facilities profiles that only
365 go as high as a standard post-doctoral grade. We note that these job families were
366 legitimised in the UK following negotiation between campus trade unions (University and
367 Colleges Union (UCU), Unite and Unison) and representatives of the employers. Such a
368 change may therefore require engagement of Unions across the sector to advocate on
369 behalf of all research institution employees.

370

371 The professionalisation of TIRs could be further accelerated if larger mainstream funders
372 created TIR fellowships (see similar recommendations by Teperek et al. (2022) and UKRI-
373 Research England (2022)). This would require a cultural change from funders to value long

374 term investment in individual TIRs, and infrastructural change in how funds are distributed. In
375 our idealised future, once role profiles are professionalised and standardised, institutions
376 may ensure the continuity of support without the need for individual fellowships, through
377 dedicated funding.

378 **5. Conclusion**

379 The Scientific Reform Movement has brought attention to the opportunities and needs
380 surrounding research teams with diverse expert skills. Nevertheless, there is considerable
381 work to ensure that the individuals who contribute significantly to effective teams (TIRs) are
382 appropriately acknowledged and rewarded. TIRs often experience a lack of autonomy, have
383 limited opportunities for career development, and face prejudice for deviating from the
384 traditional academic credit system.

385

386 While acknowledging that there are significant challenges faced by TIRs in the current
387 academic model, we highlighted three cases where there have been efforts to
388 professionalise TIR profiles, thereby creating communities, recognisable standards in
389 training, development opportunities, and collective advocacy.

390

391 To support further improvements in integrating TIRs into academic research systems, we
392 suggest four system-level changes:

393

394 1) Shift the focus of academic research to achieving excellence in the *process* of the
395 endeavour, not the *prestige* of the outputs. Acknowledging that no output is necessarily final,
396 we advocate for frequent or continuous public documentation (publication) of every stage of
397 research, allowing for recognition of various contributions at each stage.

398

399 2) Expand the system for recognising contributions, for example through the expansion of
400 CRediT, the incorporation of version-controlled attribution, and the acknowledgement of
401 less-visible work such as service to the institution or profession.

402

403 3) Create mechanisms for validating the quality and impact of non-journal outputs akin to
404 peer review, noting that this will require infrastructural development in the delivery of review,
405 and agreement on review standards for different output types.

406

407 4) Standardise and professionalise roles and pathways for career development, culminating
408 in an academic career track which is distinct from the current "researcher" versus "non-

409 researcher" dichotomy and, importantly, not restricted in the level of influence or reward
410 achievable.

411

412 These proposals are offered at a time of increasing focus on improving the bureaucratic
413 efficiency of academia (Independent Review of Research Bureaucracy, 2022), increasing
414 support for the open dissemination of research outputs (Concordat Working Group, 2016;
415 *OSTP Public Access Memo*, 2022; UNESCO, 2021), calls to improve the broader culture of
416 academia (COARA, 2022; Wellcome Trust, 2020), and the existing commitments to improve
417 TIR positions (Technician Commitment, 2020). If we seek to actualise the reform and
418 ambitions of motions such as the San Francisco Declaration on Research Assessment
419 (DORA, 2012), we must acknowledge that there is significant scope to modernise the culture
420 and tools we use to recognise and reward contributions. Systemic changes that improve the
421 access of TIRs to career satisfaction will impact the reward and recognition processes
422 relevant to the entire academy, making room to acknowledge, value and celebrate more
423 diverse contributions and contributors to our work.

424 **Acknowledgements**

425 We thank Dylan Roskam-Edris for helpful comments and Julien Colomb for sharing
426 resources. Many thanks to Sarahanne Field for editing this issue and for her support and
427 patience in the process. Thanks to Yo Yehudi for input on the abstract and title of this work.
